# Exception-handling

An exception is a runtime error which can be handled by the programmer. All exceptions are represented as classes in Python.

Type of Exception:-

Built-in Exception – Exceptions which are already available in Python Language. The base class for all built-in exceptions is BaseException class.

User Defined Exception – A programmer can create his own exceptions, called user-defined exceptions.

# All exceptions are represented as classes in Python.

There are 2 stages where error may happen in a program

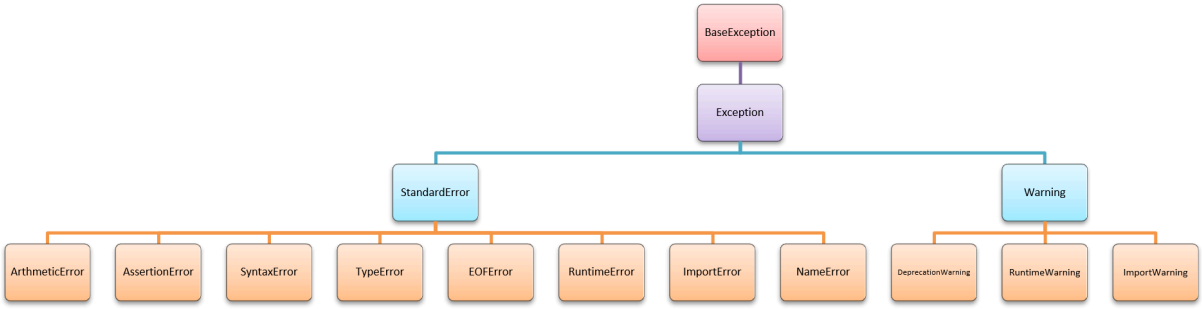
During compilation -> Syntax Error

- Something in the program is not written according to the program grammar.
- Error is raised by the interpreter/compiler
- You can solve it by rectifying the program

  Other examples of syntax error

- Leaving symbols like colon,brackets
- Misspelling a keyword
- Incorrect indentation
- empty if/else/loops/class/functions

During execution -> Exceptions



# Exception Description

ArithmeticError: Raised when an error occurs in numeric calculations

AttributeError: Raised when attribute reference or assignment fails Exception Base class for all exceptions

EOFError: Raised when the input() method hits an "end of file" condition (EOF)

ImportError: Raised when an imported module does not exist

IndentationError: Raised when indentation is not correct

IndexError: Raised when an index of a sequence does not exist

KeyError: Raised when a key does not exist in a dictionary

NameError: Raised when a variable does not exist

SyntaxError: Raised when a syntax error occurs

TypeError: Raised when two different types are combined

ValueError: Raised when there is a wrong value in a specified data type

ZeroDivisionError Raised when the second operator in a division is zero

```

# Why is it important to handle exceptions

When an exception occurs, the program terminates suddenly.

Suddenly termination of program may corrupt the program.

Exception may cause data loss from the database or a file.

# how to handle exceptions

# Try – The try block contains code which may cause exceptions.

Syntax-

try:

```
    statements
```

# Except – The except block is used to catch an exception that is raised in the try block. There can be multiple except block for try block.

Syntax-

except ExceptionName:

```
    statements
```

# Else – This block will get executed when no exception is raised. Else block is executed after try block.

Syntax-

else:

```
    statements
```

# Finally – This block will get executed irrespective of whether there is an exception or not.

Syntax-

finally:

```
    statements
```

# We can write several except blocks for a single try block.

We can write multiple except blocks to handle multiple exceptions.

We can write try block without any except blocks.

We can not write except block without a try block.

Finally block is always executed irrespective of whether there is an exception or not.

Else block is optional.

Finally block is optional.

# example 1

try:

    Statement

except ExceptionClassName:

    Statement

# example2

try:

    Statement

except ExceptionClassName:

    Statement

else:

    Statement

finally:

```
    Statement
```

# example 3

try:

```
    Statement
```

except ExceptionClassName1:

```
    Statement
```

except ExceptionClassName2:

```
    Statement
```

finally:

```
    Statement
```

# example4

try:

```
    Statement
```

# how to write except block

1.With the Exception Class Name

```
except ExceptionClassName:

    Statement
```

2.Exception as an object

```
except ExceptionClassName as obj:

    Statement
```

3.Multiple Exception within tuple

```
except (ExceptionClassName1,
ExceptionClassName2, ExceptionClassName3, …… ):

    Statement
```

4.Catch any Type of Exception

```
except:

   Statement
```

In [17]:
```
# let's create a file
with open('sample.txt','w') as f:
  f.write('hello world')

```

# Assert Statement

The assert Statement is useful to ensure that a given condition is True. If it is not true, it raises AssertionError.

Syntax:- assert condition, error_message

If the condition is False then the exception by the name AssertionError is raised along with the message.

If message is not given and the condition is False then also AssertionError is raised without message.

In [10]:
```
n=int(input("enter int"))
assert n>5,"enter valid number"
```

```
enter int4
---------------------------------------------------------------------
----
AssertionError                            Traceback (most recent call l

      1 n=int(input("enter int"))
----> 2 assert n>5,"enter valid number"

AssertionError: enter valid number
```

# User Defined Exception

A programmer can create his own exceptions, called user-defined exceptions or Custom Exception.

1.Creating Exception Class using Exception Class as a Base Class

2.Raising Exception

3.Handling Exception

# Creating Exception

# We can create our own exception by creating a sub class to built-in Exception class.

class MyException(Exception):

```
        pass
```

class MyException(Exception):

```
        def __init__(self, arg):

                self.msg = arg
```

In [11]:
```
class BalanceException (Exception):
    #pass
    def __init__(self, arg):
        self.msg = arg

def checkbalance():
    money = 10000
    withdraw = 9000
    try:
        balance = money - withdraw
        if(balance<=2000):
```

```
            raise BalanceException('Insufficient Balance')
        print(balance)
    except BalanceException as be:
        print(be)

checkbalance()
```

```
Insufficient Balance
```

# Raising Exception

raise statement is used to raise the user defined exception.

raise MyException('message')

In [16]:
```
# raise Exception
# In Python programming, exceptions are raised when errors occur at ru
# We can also manually raise exceptions using the raise keyword.

# We can optionally pass values to the exception to clarify why that ex

raise ZeroDivisionError('aise hi ')
# Java
# try -> try
# except -> catch
# raise -> throw
```

```
---------------------------------------------------------------------
----
ZeroDivisionError                         Traceback (most recent call l
ast)
<ipython-input-16-97b461be5f2b> in <module>
      5 # We can optionally pass values to the exception to clarify why
that exception was raised
      6
----> 7 raise ZeroDivisionError('aise hi ')
      8 # Java
      9 # try -> try

ZeroDivisionError: aise hi
```

In [18]:
```
money = 10000
withdraw = 9000
try:
        balance = money - withdraw
```

```
        if(balance<=2000):
            raise BalanceException('Insufficient Balance')
        print(balance)
except BalanceException as be:
        print(be)
```

```
Insufficient Balance
```

In [12]:
```
class Bank:

  def __init__(self,balance):
    self.balance = balance

  def withdraw(self,amount):
    if amount < 0:
      raise Exception('amount cannot be -ve')
    if self.balance < amount:
      raise Exception('paise nai hai tere paas')
    self.balance = self.balance - amount

obj = Bank(10000)
try:
  obj.withdraw(15000)
except Exception as e:
  print(e)
else:
  print(obj.balance)
```

```
paise nai hai tere paas
```

In [13]:
```
class MyException(Exception):
  def __init__(self,message):
    print(message)

class Bank:

  def __init__(self,balance):
    self.balance = balance

  def withdraw(self,amount):
    if amount < 0:
      raise MyException('amount cannot be -ve')
    if self.balance < amount:
      raise MyException('paise nai hai tere paas')
    self.balance = self.balance - amount

    num = [3, 4, 5, 7]
    if len(num) > 3:
        raise Exception( f"Length of the given list must be less than
except Exception as e:
    print(e)
```

```
Length of the given list must be less than or equal to 3 but is 4
```

# Handling Exception

Using try and except block Programmer can handle exceptions.

try:

        statement

except MyException as mye:

        statement

In [19]:
```
# catching specific exception
try:
  m=5
  f = open('sample.txt','r')
  print(f.read())
  print(m)
  print(5/2)
  L = [1,2,3]
  L[100]

except Exception as e:
  print(e)
```

```
hello world
5
2.5
list index out of range
```

# Error vs Exception

An exception is an error that can be handled by a programmer.

An exception which are not handled by programmer, becomes an error.

All exceptions occur only at runtime.

Error may occur at compile time or runtime.

# Error vs Warning

It is compulsory to handle all error otherwise program will not execute, while warning represents a caution and even though it is not handled, the program will execute.

Errors are derived as sub class of StandardError, while warning derived as sub class from Warning class.
